FULL PHONETIC COMPLEMENTATION, SEMANTIC CLASSIFIERS, AND SEMANTIC DETERMINATIVES IN ANCIENT MAYAN HIEROGLYPHIC WRITING

David F. Mora-Marín

Abstract

This paper discusses a little understood spelling practice of Mayan hieroglyphic writing, the use of full phonetic complementation of logograms, and some implications derived from this practice, particularly when compared with similar practices in other logosyllabic scripts from around the world (e.g., Egyptian and Luvian), which suggest that such practice existed in association with semantic classifiers. Also, a preliminary distinction between two types of semantograms is made: semantic classifiers and semantic determinatives. Previous discussions of both types of signs are reviewed, and it is proposed that the two are more widespread and important in Mayan writing than previously thought. The implications of these results are clear: Mayanists, particularly epigraphers, need to pay more attention to this distinction in their decipherment efforts, as well as in any future philological and paleographic endeavors. The paper concludes with a proposal for the interrelationship between the stylistic evolution of graphemes and the development of semantic classifiers and determinatives.

This article addresses three traits of Mayan hieroglyphic orthography: semantic determinatives, semantic classifiers, and full phonetic complementation of logograms. The first trait, semantic determinatives, has received very little attention to date, with a few original exceptions (Justeson 1986:447–449; Kelley 1976:206–211; Schele 1983:19–21), as well as a recent claim that such signs are not a productive category of the script at all (Zender 1999). The second trait, semantic classifiers, has only recently been recognized as a useful orthographic category in Mayan writing (Hopkins 1994; Hopkins and Josserand 1999). The third trait has not, to this author's knowledge, received a detailed or even cursory treatment in previous literature, except for a passing mention by Houston and Coe (2003:154), who assert, without elaboration, that "pattern of fully syllabic spellings accompanied by logographs is no longer thought to characterize Maya writing." Thus, there is a current need for discussion of these orthographic principles aimed at testing their validity and promoting their systematic study and accounting in the decipherment process. It is a well known and accepted fact that such conventions characterize a plurality of scripts from the Old World, such as Sumerian, Egyptian, Chinese, Hittite, Luvian, and Elamite, among others—scripts that share many structural characteristics with Mayan. Consequently, it is a worthwhile pursuit not only to investigate such traits for the sake of more fully understanding Mayan script, but also to elaborate a basis for diachronic and synchronic comparisons with similar scripts elsewhere. This paper argues that such traits do characterize Mayan writing and that it is possible to study them both synchronically, from a functional perspective, and diachroniconically, with the goal of understanding not only the evolution of the script but also the scribal practices and associated cognitive processes responsible for such evolution.

COMPARATIVE AND THEORETICAL FRAMEWORK

Before presenting the framework used in this paper, a few notational preliminaries are in order. I follow the transcription conventions of Mayan signs using catalog numbers proposed by Thompson (1962: 31–34) and Macri and Looper (2003:363–375), and the transliteration conventions of Mayan sign values proposed by Fox and Justeson (1984), which include, among others, the following: the use of bold minuscule letters for syllabograms, which consist of consonant–vowel (CV) phonetic values (e.g., T25/AA1 **ka**); the use of bold majuscule letters for logograms, which represent CVC roots (e.g., T544/XQ3 **K'IN** 'day, sun') or CVCVC words (e.g., **KAB'AN** 'earthquake [day name])'; and the use of superscript labels to represent semantic determiners and semantic classifiers (e.g., [ROYAL.HEADBAND]**'AJAW**, or [RH]**'AJAW**, for short, for the use of the royal headband determinative on T1008 to represent *'ajaw* 'lord, ruler'), among others. I use $<?>$ to represent the glottal stop that is often represented in practical orthographies with $<'>$. Also, the literature on Old World scripts shows a proliferation of terms to refer to the orthographic categories discussed here. For consistency the following are used: semantograms, semantic classifiers, and semantic determinatives. A semantogram is a type of sign with semantic value only; it may be either a classifier or a determinative. Semantic classifiers are adjacent to a logographic, logophonetic, or phonetic spelling of a word; they do not disambiguate between alternative readings of such spellings but simply indicate, visually, what the semantic category or domain of the spelled word is. Semantic determinatives are placed adjacent

to a logographic, logophonetic, or phonetic spelling of a word; they disambiguate between alternative orthographic values—not necessarily only between alternative words spelled out by the same sign or sequence of signs, but more specifically between alternative orthographic values, of whatever type, of the same sign or sequence of signs. The term *logophonetic* is used above, rather than *logosyllabic*, to include scripts without syllabograms but with phonetic signs of other types, which may be used in conjunction with logograms to spell a word. For example, Egyptian uses logograms and consonantal signs, often in combination, while Mayan uses logograms and syllabograms, often also in combination, resulting in two types of mixed logophonetic spellings. The term *logosyllabic* is used to refer to mixed spellings in Mayan and other scripts with logographic and syllabographic signs. One last clarification: semantograms are *not* ideograms. Semantograms are not read

aloud but, instead, are used in direct association with signs that are read aloud—whether logograms or syllabograms. They are also optional to a lesser or greater extent. Ideograms, according to the traditional definition, are signs that convey an idea only and that can be used on their own to convey that idea. In the latter case, ideograms cannot be considered optional as semantograms are and are not currently known to exist in Mayan writing.

The framework presented here is derived from a review of the relevant practices in other scripts, followed by a discussion of general and specific characteristics and the elaboration of an adequate terminology to account for such characteristics. With regard to Egyptian writing, Davies (1998:104) refers to semantic classifiers as "eneric determiners" or "taxograms." These assign a semantic domain or category to an adjacent, usually preceding spelling of a word, whether logographic or phonetic in nature. Figure 1a–b shows the use of

Figure 1. Cross-script comparative examples. (a) Egyptian spelling: jt^MAN for *jt* 'father'; (b) Egyptian spelling: jt^MAN for *jt* 'father'; (c) Egyptian spelling: 'm-t^WOMAN for *'m.t* 'wife'; (d) Egyptian spelling: nb-t^WOMAN for *nb.t* 'lady, mistress'; (e) Egyptian spelling: w-n^EVIL.BIRD 'mistake'; (f) Egyptian spelling: w-n^LOCK.OF.HAIR 'bald'; (g) Egyptian spelling: w-n^CITY 'Hermopolis'; (h) Egyptian spelling: w-n^SUN.RAYS 'light'; (i) Chinese: *hsiang*^MAN 'image'; (j) Chinese: *hsiang* 'elephant'; (k) Sumerian logogram, **KU** 'to eat', formed as semantic compound by juxtaposition of two signs with their own logographic values—HEAD and BREAD; (l) Egyptian partial logophonetic spelling of 'star' as **s-b-SBZ**; (m) Egyptian full logophonetic spelling of 'star' as **s-b-Z-SBZ**.

the classifier MAN to indicate that the spelled-out words refer to male persons: **j-t**^MAN for *jt* 'father' and **nb**^MAN for *nb* 'lord'. In neither case is the classifier MAN, depicting a seated man, read aloud, as if used logographically, for the intended reading was not 'father man' or 'lord man', but simply 'father' and 'lord', respectively. Similarly, Figure 1c shows the spelling **'m-t**^WOMAN for *'m.t* 'wife', while Figure 1d shows the spelling **nb-t**^WOMAN for *nb.t* 'lady, mistress'. In this case, too, the classifier WOMAN is not pronounced. It is merely a visual cue, classifying the phonetically spelled word as to its semantic domain, just as is the case of the classifier MAN. Davies (1998:106) suggests that semantic classifiers used thus could have served to facilitate reading of a text. Rather than having to recognize a word by first putting together the phonetic spelling and then, from context, determining what the correct reading for that spelling would be in a given situation, the classifier sign—always a pictorial sign that could be used logographically on its own in other contexts—would allow the reader to immediately identify the correct domain of the intended word. A common type of classifier was the oval cartouche that was used to frame proper names of individuals and some gods. It allowed the reader to immediately identify visually the location of such proper names.

Egyptian also employs semantic determinatives, referred to as "determiners" by Davies (1998); signs that are used to disambiguate otherwise homophonous spellings by indexing, semantically, the domain of the intended word. These are similar to semantic classifiers and, like classifiers, they are not read aloud. The difference lies in that a given semantic classifier may be applied to a host of different spellings of different words that belong to the same category (e.g., MAN with the spellings for 'father' and 'lord'; WOMAN with the spellings for 'wife' and 'lady, mistress'), while a given semantic determinative could in principle be applied to a single spelling to disambiguate between two possible readings of the same spelling (Davies 1998:106), for one, and more generally, their function was one of disambiguation between homophonous spellings (not necessarily homophonous words, which may have differed in their vowels, which the script did not represent), not classification per se. For instance, the phonetic spelling **w-n** could spell a multitude of words, among them those in Figure 1e–h: **w-n**^EVIL.BIRD 'mistake', **w-n**^LOCK.OF.HAIR 'bald', **w-n**^CITY 'Hermopolis', and **w-n**^SUN.RAYS 'light'. Chinese writing developed similar conventions. An example, in Figure 1i–j, shows the use of the sign MAN to disambiguate the otherwise homophonous *hsiang*^MAN 'image' from *hsiang* 'elephant'. The logogram itself is originally an ELEPHANT sign, which explains why the determinative MAN was added to the sign to index the homophonous *hsiang* 'image' instead. Mayan writing typically does not use semantic determinatives in this way. For example, the spelling T561.23 (XH3.1G1) **CHAN-na** could represent pre-Ch'olan **cha'n* 'sky', **chaan* 'snake', or **chan* 'four'. Thus, such spellings would have been ideal for disambiguation by means of a semantic determinative. However, in actuality there is no example where a semantic determinative is used with such spelling. T561.23 **CHAN-na** could be used to spell any of these three lexemes, and so could T/AC6 **CHAN** 'snake', and T1010/SN4 or IV/004 **CHAN** 'four' (Houston 1984; Lounsbury 1984). As shown below, semantic determinatives had a different function in Mayan; to distinguish between *types* of orthographic values, such as between a logographic value and a syllabographic value, as with the case of ^SPHERULES T710/MZS **CHOK** 'to throw down' versus T710/MZR **ye**, or to distinguish between values of the same logogram with very different phonetic realizations, such as between ^MOLE PC4 **XIB'** 'male' versus T1008 **WINIK** 'man, person'.

Another type of orthographic convention needs to be discussed. This is the case of logographic signs composed of two other pictorially motivated signs, often themselves logograms when used separately in other contexts, that together yield a third value, typically a logographic value, that is contextually associated with the pictorial or logographic values of the separate signs. Rogers (2005:89) refers to these as semantic compounds. Zender (1999) refers to such signs in Mayan as composite signs, as discussed below. Figure lk is a typical example, this time from Sumerian Cuneiform, where two logograms, the first **SAG** 'head', depicting a person's head, and the second **NINDA** 'bread', depicting a piece of bread, are put together in a contextually appropriate arrangement, with the sign BREAD placed on the mouth of the HEAD sign to derive the new logographic value **KU** 'to eat'. Sumerian shows other examples, such as the compound sign for **NAN** 'drink', consisting of the signs **SAG** 'head' and **A** 'water', arranged also in a contextually appropriate manner. Another example is made up by the signs **MUNUS** 'woman' and **KUR** 'mountain', combined into a compound sign read **GEME** 'female slave', probably because "slaves typically came from the mountain ranges to the East" (Rogers 2005:91). At first, this may not seem to be a case of semantic classifiers or determinatives until the facts are considered more carefully. The **SAG** 'head' sign, for instance, serves to indicate the semantic category or domain of both the **NAN** 'drink' and **KU** 'to eat' logograms; they are both actions carried out with the mouth. Thus, it is a semantic classifier. The **A** 'water' and **NINDA** 'bread' signs, at the same time, serve to distinguish or disambiguate between related alternatives—between actions carried out with the mouth—by "determining" one as 'drinking' and the other as 'eating', respectively. Thus, they function as semantic determinatives.

At this time it is necessary to bring mixed spellings, those consisting of logograms and phonetic complements, into the picture, particularly in relation to the practice of full phonetic complementation of logograms. An illustrative case is that of Luvian (Melchert 2004:578). The logogram COW representing /wawi: s/, could be spelled with phonetic complements as follows; **COW-wi/wa-sa**~^COW**wi/wa-wi/wa-sa**. (Luvian Hieroglyphic writing did not have separate CV signs to distinguish between /i/ and /a/ vowels; hence, the sign **wi/wa** was read as either *wi* or *wa* depending on context.) The first example is a case of a logogram followed by a partial phonetic spelling (**COW-wi/wa-sa**). Luvian specialists regard the second example (^COW**wi/wa-wi/wa-sa**) as a case of the logogram COW being used as a "semantic determinative." According to Melchert (personal communication 2004), the logogram COW was used as a determinative for semantically related items (e.g., 'cow' or 'bull'). This function agrees, then, with that of semantograms defined above as semantic classifiers, not "determinatives," a term that has clearly been used rather loosely in the literature on writing systems until relatively recently (Rogers 2005). As Melchert has also explained, these semantic classifiers were not obligatory, so one may find a word spelled out phonetically without a preceding determinative, or a logogram followed by a partial phonetic spelling as a complement. Hawkins (2003:158, 163) notes a basic difference in usage between the "Empire" and "Late" script in the case of Luvian script. He notes that they are not only of "more widespread use [in] the Late period," but that in such period "it is somewhat more difficult to distinguish between actual determinatives and logograms with more than one reading, especially given the Late Hieroglyphic practice, unusual in Cuneiform, of following a logogram with a full phonetic writing."

Akkadian also uses semantograms as semantic classifiers, not as determinatives. Words spelled logographically or syllabographically may both take classifiers (Huehnergard and Woods 2004). Classifiers were optional, and when present they were silent. An example is WOOD, which was used before signs representing wooden objects, as in the spelling ^{WOOD}GU.ZA (i.e., WOOD-THRONE) = *kussûm* 'throne'. Also, out of the known Akkadian sign inventory of about 600 signs, only 19 determinatives were in common use. This is more interesting when one considers that out of the total inventory of signs, only a small subset is known for any specific period of time. Old Babylonian used about 150 signs, for example, as pointed out by Huehnergard and Woods (2004:220).

Yet another example is the case of Elamite. Stolper (2004:66) points out that in Elamite, "most determinatives precede the word they qualify," although at least one is postposed. In addition, determinatives, which served as classifiers of semantic domains, are also derived from the larger class of logographic signs, but they may have alternative syllabographic values as well. Because of these factors, it is not clear that Elamite readers relied on the presence of signs that could be used as semantic determinatives for the purpose of word division, since a determinative could potentially be used with a syllabographic value, for example.

Egyptian also shows mixed spellings—that is, spellings involving phonetic signs (which spell consonants in the case of Egyptian) and logograms. This is not that different from the logosyllabic spelling principle in Mayan. Figure 1l–m offers two examples: the first, a partial logo-consonantal spelling, **s-b-SBZ**, and the second, a full logo-consonantal spelling, **s-b-Z-SBZ**, both for *sbZ* 'star'. Interestingly, in Egyptian, semantic classifiers and determinatives are often used in combination with purely phonetic spellings of words, typically spelled out in full. Thus, examples of full phonetic spellings associated with otherwise logographic signs should be of interest to Mayan epigraphers. In scripts such as Egyptian, such spellings are quite commonly associated with semantograms, not just logograms.

Based on this evidence, several conclusions can be drawn. Where semantic determiners are concerned, it can be said that their primary function is to distinguish at least one lexical orthographic value of a sign from another—as with the case of Chinese *hsiang* 'elephant' and *hsiang*^{MAN} 'image', both based on the same logogram, a logogram originally based on the sign ELEPHANT. Where semantic classifiers are concerned, their primary function is to assign a spelling—whether a logographic or phonetic one—a semantic domain, possibly to accelerate the reader's ease of recognition of the intended value. Finally, evidence from other scripts suggests that we should expect Mayan writing to contain examples of logograms associated with full phonetic spellings of their referents.

FULL PHONETIC COMPLEMENTATION IN MAYAN SCRIPT

Epigraphers have been aware of this type of spelling for some time, but it has yet to receive close attention. In fact, some epigraphers have recently denied that such spellings exist or that they are of any significance. In their review and critique of Justeson and Kaufman's (1993, 1997) proposed decipherment of Epi-Olmec/Isthmian writing, Houston and Coe (2003:154) state the following:

> Inexplicable forms are compelled by [Justeson and Kaufman's (1993)] decipherment [of Epi-Olmec writing], such as phonetic complements for numbers of star signs, which would seem to be inherently obvious in their value, or full phonetic spellings of words before logographic spellings of the same. . . . In no case do Maya glyphs require such elaborations to confirm the spelling of "star" signs. Moreover, and contrary to a proposal made in the 1970s by Floyd Lounsbury, this last pattern of fully syllabic spellings accompanied by logographs is no longer thought to characterize Maya writing, and there is very little reason to think that such redundancy would occur in Isthmian [Epi-Olmec].

This claim is unusual and unsupported, for no author has ever systematically sought such spellings, much less described them at length. Regardless of the situation in Epi-Olmec/Isthmian writing, a systematic, though not necessarily thorough, search by the present author has yielded several cases in which ancient Mayan scribes chose to provide full phonetic complements to a logogram representing the same referent as the full phonetic spelling, as shown below. Kelley (1976:176), for his part, identified at least one example of this type of spelling—that of the month name *Mac* as **ma-MAK-ka**, which he transcribed as *(ma)mac(caca)*, for he assumed at the time that doubled signs were likely not repeated for aesthetic purposes but were instead "functional." Interestingly, Kelley also addressed the alleged problem of "redundancy," in reaction to Thompson's (1963:137–138) assessment of such a reading as a "great exaggeration," by stating: "[Thompson] suggests that this would be a great exaggeration—a suggestion with which I must agree, only pointing out that it is the Mayas' exaggeration, not mine" (Kelley 1976:176).

Normally, a phonetic complement is graphically preposed (prefixed or superfixed) or graphically postposed (suffixed or subfixed) to a logogram, as shown in Figure 2a–b. There are even examples where a preposed phonetic complement and a postposed phonetic complement occur simultaneously (Figure 2c), where T566 **MAN** appears with preposed (superfixed) **ma-** and postposed (subfixed) **–na**. Another, relatively common example of such arrangement is **wi-WINIK-ki**, for *winik* 'man, person', not illustrated here. The case of **(ma-)MAN(-na)** is different, however, from cases such as **(wi-)WINIK(-ki)**, in that the former is a case of full phonetic complementation, meaning that the whole word is spelled out phonetically, while the second example is not, given that there is no **ni** sign to provide the *ni* sequence of *winik*.

From the point of view of visual organization of signs, yet another type of mixed spelling is possible in Mayan writing and is attested widely in other scripts with both logographic and phonetic signs. In this third type, scribes applied phonetic complements in full either before or after an otherwise logographic sign, as opposed to both before and after the logogram (Mora-Marín 2001: 75). An example from the Dresden Codex (Figure 1d) shows **'EM(I)-'e-mi** for *ehm-i-Ø* descend-PLN-3sABS 's/he/it goes/comes down' (Schele and Grube 1997). The logogram, T227a, is followed by two phonetic signs that serve both as phonetic complements and to spell the plain status suffix *–i*. This example should alert epigraphers to the possibility of logosyllabic spellings of verbs of the form LOGOGRAM-CV-CV in which the syllabographic sequence is not spelling a suffix or sequence of suffixes (e.g., **HUL-li** for *hul-i* 'it/s/he arrived here', **CHUM-wa-ni** for *chum-wan-i* 'it/s/he sat down') but the whole verb by itself. Also, certain spellings of T539/645 **WAY** 'alter ego; shape-shifter', seen in Figure 1e–f. One may find it as **wa-ya-WAY** or **WAY-wa-ya**. Clearly, epigraphers have had no trouble recognizing the practice involved. In fact, these spellings were crucial to the decipherment of T539 as **WAY** 'alter ego; shape-shifter', achieved independently
Figure 2. (a) Example of preposed phonetic complementation: **(wa-)WAY**; (b) example of postposed phonetic complementation: **WAY(-ya)**. Drawings by the author after Houston and Stuart 1989:3, Figure 1; (c) example of logogram with preposed and postposed phonetic complements on Palenque Temple XIV Tablet: **(ma-)MAN(-na)**. Drawing by the author after drawing by Linda Schele (www. famsi.org); (d) Example of logogram with postposed phonetic complements: **'EM(I)-'e-mi**. Dresden Codex 20b. After Kingsborough version (www.famsi.org/mayawriting/codices); (e) example of logogram with preposed phonetic complements: **(wa-ya-)WAY**; (f) example of logogram with postposed phonetic complements: **WAY(-wa-ya)**. Drawings by the author after Houston and Stuart 1989:3, Figure 1; (g) example of logogram with postposed phonetic complements: **MAN(-ma-na)**, Yaxchilan. Drawing by the author after drawing by Linda Schele (no. 6201, www.famsi.org); (h) example of **K'UHUL-'IX(-'i-xi) K'AN-to-ko**. Bonampak Sculptured Stone 4:G2-H2. Drawing by the author after detail from a drawing by Ian Graham in Wagner 2003:2; (i) spelling of **'u-'UNIW-ni-wa** for *uniw* '14th month name' on Dos Pilas Stela 8. Drawing by the author; (j) spelling **K'INICH-[JANAB']PAKAL-pa-ka-la** on the West Tablet of the Temple of Inscriptions at Palenque. Detail of a drawing by Linda Schele.

by Grube (Schele and Freidel 1990), on the one hand, and by Houston and Stuart (1989), on the other. Another example is that of T566 **MAN**, a sign whose meaning is still unclear but that appears in one instance as **MAN-ma-na** (Figure 1g), contrasting with the case shown above as **ma-MAN-na** in Figure 1c only in the placement of the syllabograms with respect to the logogram.

Another clear example is found at Bonampak (Figure 2h), where one finds logographic T1000a,b/1001c/1002 **'IX(IK)** followed by purely syllabographic **'i-xi**. If one reads the female

head T1000a,b/1001c/1002 as **'IXIK** (Stuart et al. 1999; Wagner 2003), then the **'i-xi** sequence still functions as a phonetic complementation sequence—one showing abbreviation or underspelling. Hopkins (personal communication 2006) has offered a different interpretation: the sequence could be two separate titles, rather than one, read **K'UHUL-'IXIK, 'i-xi K'AN-to-ko** 'Holy Lady, Ms. K'an Tok'. I agree with Hopkins that this is certainly a plausible interpretation. But if the first interpretation is correct, this would be another case of postposed,

full phonetic complementation in the sense that the scribe meant to spell out phonetically the whole word after its corresponding logogram, whether the final consonant was underspelled or not (though this would not have been the case if we assume T1000a,b/1001c/1002 was simply **'IX** in this context). This example could provide evidence for a different interpretation of the orthographic function of this type of spelling, which might suggest that scribes were not conceptualizing them as cases of a semantic classifier followed by a word representing a member of its semantic domain.

Two more examples are worth considering. One is the frequent spelling of Pacal, the king of Palenque, as **PAKAL-pa-ka-la**, with the SHIELD logogram containing the **JANAB'** logogram as an infix (Figure 2i). More is said about this example below. Another example, reminiscent of the **ma-MAN-na** spelling (Figure 2c), is that of the month name *uniw* as **'u-'UNIW-ni-wa** (Figure 2j), an example that should lead us to expect the future finding of spellings such as **wi-WINIK-ni-ki**.

We may classify the different kinds of phonetic complementation of logograms in Mayan as follows:

(1) PHONETIC COMPLEMENTATION TYPOLOGY IN MAYAN
    a. Partial Phonetic Complementation
        i. Pre-posed phonetic complement:
            a. **wa-WAY** for *way* 'shape-shifter/co-essence' (Figure 2a)
        ii. Post-posed phonetic complement:
            a. **WAY-ya** for *way* 'shape-shifter/co-essence' (Figure 2b)
        iii. (Special cases: Infixed phonetic complement)
    b. Complete Phonetic Complementation
        i. Pre-posed and post-posed phonetic complements:
            i. **ma-MAN-na** (Figure 2c)
            ii. **'u-'UNIW-ni-wa** (Figure 2i)
        ii. Pre-posed phonetic complements:
            i. **wa-ya-WAY** (Figure 2e)
        iii. Post-posed phonetic complements:
            i. **WAY-wa-ya** (Figure 2f)
            ii. **MAN-ma-na** (Figure 2g)
            iii. **'IX-'i-xi** for *'ix+* 'female; small' (Figure 2h)
            iv. **K'INICH-[JANAB']PAKAL-pa-ka-la** (Figure 2i)
        iv. (Special cases: Infixed phonetic complements, not discussed here)

All of these examples are cases where a logogram is immediately adjacent to a full phonetic spelling equal to that of the logogram's referent. In Egyptian writing, this could be a case of a logogram with a complete phonetic spelling or a case of a semantogram either determining or classifying the referent of a phonetically spelled-out word. In Luvian, Akkadian, and Elamite it would be considered a case of a word categorized by a semantic classifier. Which of the three options is the case for Mayan? For a classifier function, one would expect the classifier to be associated with other words of the same category. For a semantic determinative, one would expect a disambiguating function, typically a disambiguation of homophonous or nearly homophonous words that are otherwise unrelated semantically or, alternatively, a disambiguation of different types of orthographic values—for example, one of them logographic and the other syllabographic. For a simple logosyllabic spelling, one might expect negative evidence for the other two options. And, of course, this is where the most dramatic implication for decipherment is found. If some of the logograms found in association with full phonetic spellings are being used as semantic determinatives or classifiers, then the epigrapher might be misled by such full phonetic spellings into thinking that they correspond to the value of the logogram itself. Many decipherments of the lexical values of logograms have been arrived at through associated phonetic complements—including full phonetic complements, as with the case of **wa-ya-WAY** and **WAY-wa-ya** in Houston and Stuart (1989).

SEMANTIC CLASSIFIERS IN MAYAN

The argument for the existence of signs in Mayan writing that are used to classify other signs into semantic domains—as semantic classifiers—has recently been given strong support by Hopkins (1994) and Hopkins and Josserand (1999). If these authors are correct, semantic classifiers are so pervasive in the script that epigraphers have taken them for granted. They are present in logographic signs, in which case they provide orthographic information about the semantic domain of the referent of the logogram, and in syllabographic signs, in which case they provide iconographic information about the iconic referents of the signs—but no information whatsoever about the phonetic value, since by definition semantic classifiers are divorced from phoneticism. Hopkins and Josserand (1999:4) correlate the 10 semantic classifiers they have identified for Classic period Lowland Mayan texts, listed in Table 1, with the system of noun classifiers found in some Mayan languages, such as the Greater Q'anjob'alan languages (Chuj, Jakaltek, Q'anjob'al), which contain between them about 15 categories.

Hopkins and Josserand (1999) note that while this classification system is overtly grammaticized in the noun system of the Greater Q'anjob'alan languages, it may also have been present in a more grammatically covert fashion in other Mayan languages, including the Ch'olan-Tzeltalan languages of the scribes who innovated the script. Figure 3a–d shows the use of a circular element that is apparently a semantic classifier for '(part of a) human' (Hopkins 1994:2) since it appears in signs—whether logographic or syllabographic— that iconically depict body parts. Hopkins and Josserand (1999) have identified 10 such signs, including a DOUBLE.NOTCHED element seen in Figure 3e that seems to classify animals such as jaguars (Figure 3f) and rats (Figure 3g), as well as bats, among a few others.

There are two points worth emphasizing. First, the semantic classifiers identified by Hopkins (1994) and Hopkins and Josserand (1999) apply extensively to logograms and syllabograms but do not have disambiguating functions. Thus, T529 can be transliterated as [STONE]**WITZ** 'hill, mountain'. Also, T710, whether used syllabographically as **ye** or logographically as **CHOK** 'to throw down', shows the HUMAN classifier (i.e., [HUMAN]**ye/CHOK**). Similarly, T644 can be transliterated as [HUMAN]**CHUM** 'to be seated'. Below it is suggested that, in the development of a script, semantic classifiers are more likely to precede semantic determinatives. If so, one would expect to find very few semantic determinatives in the earliest texts, given that they show perhaps only a handful of semantic classifiers such as the reflection bands (indicative of objects with polished surfaces such as jade, obsidian, any stone, etc.), but that is a topic for further research.

A possible example of a semantic classifier associated with a fully phonetic spelling of a term is found in a stucco panel from Tonina (Figure 4). In Figure 4c, the caption placed in front of a pictorial depiction of a pocket gopher is read **K'AN-na-b'a** for *k'an-al b'a* 'yellow pocket gopher' attested in Tzeltal (Bricker 1986:136). This thus shows a purely phonetic spelling of 'gopher'.

Table 1. Comparison of glyphic and linguistic classifiers by Hopkins and Josserand (1999:4)

Mayan Script Orthographic Classifiers	Q'anjob'alan (Mayan) languages with Overt Lexical Classifiers	Shared Q'anjob'alan Classifiers
ANIMAL	**ANIMAL**	nok'∼no'
HUMAN		
MAN/MALE	**MALE PERSON**	naj/wiN
WOMAN/FEMALE	**FEMALE PERSON**	ix
TREE/WOOD	**TREE**	te'
VINE	**VINE**	tx'aN/ch'aN
MAIZE	**MAIZE**	ixim
	PLANT (≠ TREE/VINE)	an/aN
STONE	**STONE**	ch'en/k'en
WATER/LIQUID	**WATER**	ha'
EARTH	**EARTH**	tx'otx'/lum
	RAIN	k'inal
	ILLNESS	yap'il
	CLOTH	k'apak/k'ap/q'ap
	SALT	atz'am
	SHEET NYLON (relatively new development)	nayleh (from Spanish)

Interestingly, the second glyph block of the caption is T758, which is iconically MOUSE/RAT and has the syllabographic value **ch'o**; this syllabographic value was undoubtedly derived acrophonically from Proto-Ch'olan *ch'ohok* 'rat' (Mora-Marín 2003). Evidence for this is found in spellings of the common expression T758:110 **CHAK-ch'o-ko** for *chak ch'ok* 'Great Youth', where *ch'ok* 'sprout (and by metaphoric extension, youth)', a term that is completely unrelated to *ch'ohok* 'rat', as in Figure 4d. In some alternative spellings of this epithet, one finds simply T758 **ch'o** with no T110 **ko**, as in Figure 4d; these spellings with T758 **ch'o** alone suggest a logographic value **CH'OK** 'youth, young', via a rebus-spelling practice based on the near-homophony between Proto-Ch'olan *ch'ohok* 'rat' and *ch'ok* 'sprout'. (It is quite likely, therefore, that a logographic value **CH'OHOK** 'rat', based on iconic transparency, could exist for T758 as well.) In Figure 4a, one finds **K'AN-na B'AH**, with T757 GOPHER, used logographically as **B'AH** 'gopher' and (through rebus) as **B'AH** 'self, head, top, first'. In this instance, there is no following T758; it is followed instead by ***'u-wa-WAY-ya** '(the) alter ego of'. The absence of T758 from this alternative spelling of the term for 'yellow pocket gopher' as **K'AN-na-B'AH** strongly suggests that it was not pronounced in the Tonina example. Also, the corresponding term for 'yellow pocket gopher' is attested as *k'anal b'a* in Tzeltal (Bricker 1986:136), not as *k'anal ba ch'o*, which is what one would expect if T758 **ch'o**/RAT were supposed to be read aloud in the Tonina example. (Kaufman [1972:101] reconstructs Proto-Tzeltalan *ch'oh* 'rata, ratón', which would be cognate with Proto-Ch'olan *ch'ohok*.) This example is sufficiently constrained orthographically (spelling variation showing presence and absence of T758) and linguistically (Tzeltal attestation) to suggest that T758 was used as a semantic classifier RODENT in the Tonina example. This is a strong case for a semantic classifier involving a phonetic spelling (i.e., **K'AN-na b'a**, where **b'a** is purely phonetic for *b'ah* 'gopher') and, in this case, a following classifier (i.e., **K'AN-na b'a**ᴿᴼᴰᴱᴺᵀ). Perhaps T758 was used as a classifier in the spelling **K'AN-na-b'a** in Figure 4c because the spelling is phonetic (i.e., T501 **b'a** for *b'a(h)* 'gopher') rather than logographic, as with T757 **B'AH** in **K'AN-na B'AH** in Figure 4a, which already uses T757 GOPHER as the logogram **B'AH** for *b'a(h)* 'gopher'.

The case also suggests that the T281 **K'AN** 'yellow, precious' logogram typically present inside T757 **B'AH/b'a** functions as a semantic classifier that specifies the biological identity of the iconographic referent of the glyph, even in contexts where it is not spelling the word for 'gopher' but is simply used to spell *b'ah* 'head, image, top' or a phonetic sequence /b'a/—which constitute the vast majority of uses of T757. As summarized above, other scripts show examples of semantic classifiers that are attested with very few words, however spelled (logographically or phonetically), sometimes even with a single word. This may be the case with the use of T281 as an infix to T757.

THE CASE FOR SEMANTIC DETERMINATIVES

To date, only a few signs are regarded as examples of semantic determinatives in Mayan writing. Kelley (1976:150) suggests that T122, a sign that depicts smoke, may have functioned as a semantic determinative in certain cases, particularly in the spelling of the word *k'ahk'* 'fire' as T122:669, as opposed to spellings such as T669:669 **k'a-k'a**, where the word was spelled out in full. Following this analysis, T122:669 would be read ˢᴹᴼᴷᴱ**k'a** for *k'ahk'* 'fire'. Bricker (1986:11–12) has suggested that T503, logographic **'IK** 'wind', could also function as a semantic sign when infixed inside T668, syllabographic **cha**, to distinguish it from T669a, syllabographic **k'a**. The disambiguation would be semantic; T503 would be associated with wind, and therefore with storms, rain, lightning, the domain of the Rain God, **CHAHUK** or **CHAK**, *chahuk*/*chahk* 'rain'. Perhaps the two best examples are the day sign cartouche and pedestal (Justeson 1978, 1986; Figure 5a), used with T528 **CHAHUK/CHAK** 'rain, lightning' (Figure 5b). Neither was obligatory. While monumental inscriptions typically require the cartouche (Figure 5c), and frequently show the pedestal (Figure 5d), painted texts on murals, pottery, and the codices often lack the pedestal, and in the codices at least, they may also lack the cartouche. Schele (1983) has also proposed that the ROYAL.HEADBAND sign was a semantic determinative; when placed on the glyph depicting the head of a man or a vulture, it would index the value **'AJAW** 'lord, ruler' (Figure 5e)—hence, the appropriateness of the transcription ᴿᴼʸᴬᴸ.ᴴᴱᴬᴰᴮᴬᴺᴰ**'AJAW** 'lord, ruler', or ᴿᴴ**'AJAW** 'lord, ruler' for short.
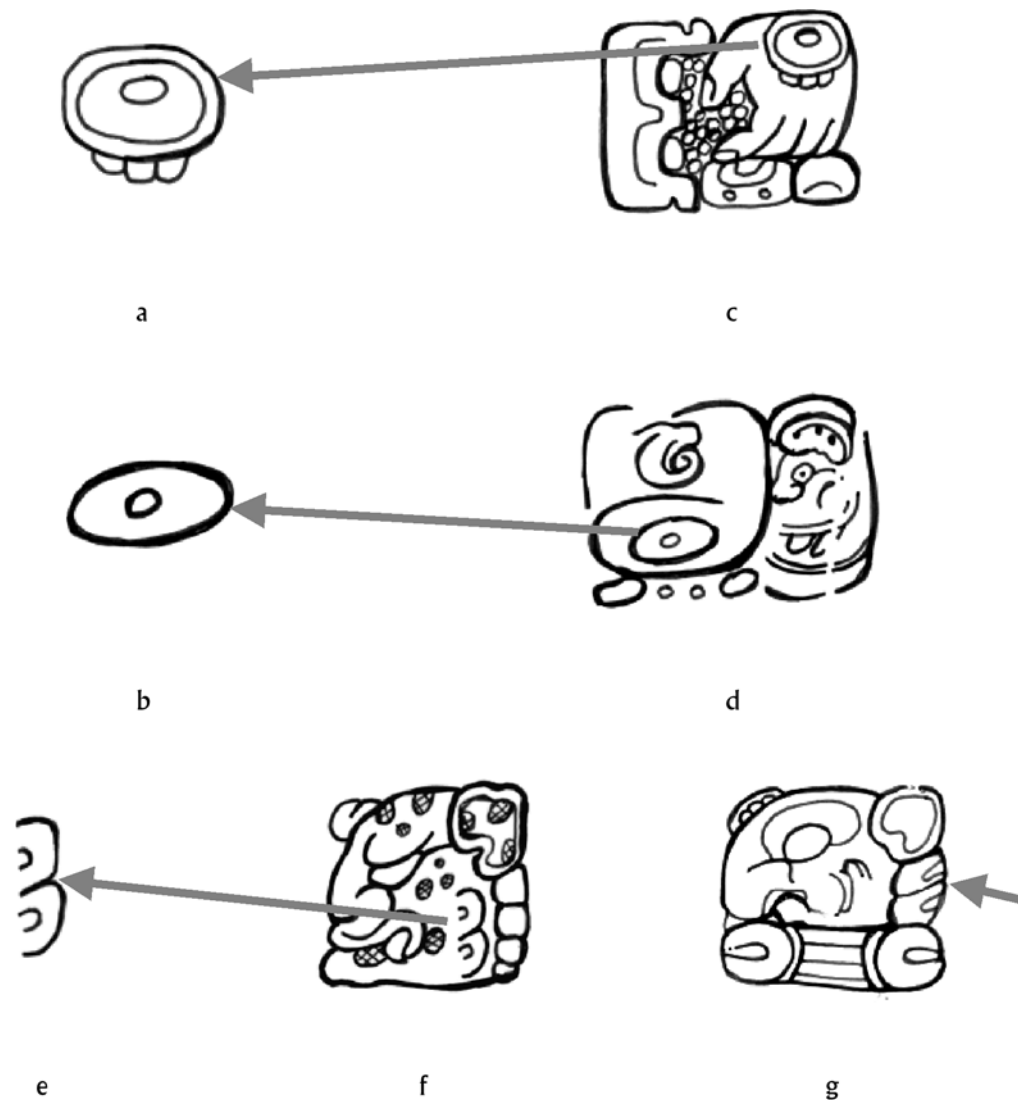

Figure 3. (a) Example of circular element; (b) another example of circular element; (c) use of circular element inside T710 **CHOK** 'to throw down'; (d) use of circular element on part corresponding to thigh on sign that depicts a torso and bent leg in seated posture (T644 **CHUM** 'seated'). Drawings from Bricker 1986:Figures 163, 187; (e) double-notched element; (f) use on **B'ALAM** 'jaguar'; (g) use on main sign (depicting a rat) of **ch'o-ko** 'rat' spelling (separate, logographic reading of RAT.HEAD sign as **CH'OK** has not been demonstrated). Drawings from Hopkins and Josserand 1999:Figure 12.

However, there are other examples of the use of semantic determinatives in Mayan writing used for orthographic disambiguation. One is illustrated by the use of the generic male head sign that corresponds approximately to T1008 (Figure 5f), which Zender (1999) has described as a basic element of a variety of composite signs with different values: **WINIK**, **XIB'**, **KELEM**, and **'AJAW**. The case of **'AJAW** is an addition to this set that I propose in this paper. This sign is made up of the generic male head sign plus the royal headband semantic determinative to be read [RH]**'AJAW** 'lord, ruler' (Figure 5e). Similarly, when T117 **wi** is added as a phonetic complement (i.e., determinative), one obtains another value: **wi-WINIK** 'person, man' (Figure 5g). Zender (1999) also notes that T220e is used with T1008, which probably has the value **KELEM** 'youth, young' in this context (Figure 5h). This is based on the assumed graphemic equivalency between T220e and T770; the latter sign (first sign in Figure 5j), which is iconically a HAND sign, has been

deciphered as a syllabogram **ke**. Therefore, the examples of T220e, also iconically a HAND sign, found before T1008 as **KELEM** are thought to read **ke-KELEM** (Figure 5i). Of course, there is evidence for the substitutional relationship between spellings such as **ke-le-ma** and the proposed logogram **KELEM**, which I do not dispute, especially since such a proposal is supported by at least two examples of the logogram subfixed by T74 **ma**. Note, however, that the HAND sign used with T1008—namely, T220e—is not identical to T770 **ke**: T220e is shaped and placed with respect to T1008 in such a way that the resulting composite sign seems to depict a thumb-sucking child, suggesting that it is used as a semantic classifier—that is, to relate the generic male head to the concept 'youth'—and raises the question of whether T220e is really equivalent to T770 **ke**. To my knowledge, T220e is only used in the T220e-**KELEM** context (i.e. as [THUMB.SUCKING]**KELEM** or [TS]**KELEM** for short). T770 **ke** is used elsewhere, as seen in the contrast between the logographic (with

T220e) and syllabographic (with T770) spellings of the term in Figure 5j.

T1008, the generic male head, was a potentially polyvalent sign that required a phonetic or semantic determinative for disambiguation. The default logographic value of this sign, when lacking the spot on the cheek, may have been **WINIK** 'man, person' (Figure 5g) rather than **XIB'** 'male', since the latter reading seems to require the spot on the cheek (Figure 5f). The spot on the cheek therefore may have been a semantic determinative for the reading **XIB'** 'male' of T1008: ^{SPOT}**XIB'** 'male'. I have yet to find evidence to suggest that T1008 was also a semantic classifier by itself, as T1000a,b/1001c/ 1002 may have been. Evidence could come in the form of spellings such as T1008-**wi-ni-ki** contrasting with spellings such as T1008-**'a-ja-wa**, but I know of no such spellings. Hence, I use asterisks—for example, *T1008-**wi-ni-ki**, *T1008-**'a-ja-wa**—to indicate

that such spellings are unattested but might be possible if T1008 is in fact a semantic classifier.

Another interesting example is that of T710 (Figure 6). As a plain hand, T710 has a syllabographic value **ye** (Figure 6a–b), probably derived acrophonically from *ye'* 'to grab with, to carry by the hand' (Aulie and Aulie 1998:158), as Hopkins (personal communication 2006) has observed, but when the SPHERULES icon is present, T710 has the logographic value **CHOK** 'to throw (down)' (Figure 6c–d), even if the hand gesture is identical to that used for the syllabogram **ye**. There are very few instances where T710 lacks the spherules but must nonetheless be read as **CHOK**. These are very rare, and from context is it is always clear that **CHOK** rather than **ye** was meant. However, there are no cases, to my knowledge, of T710 meant to be read as **ye** in which the spherules are
Figure 6. (a) T710 as syllabogram **ye**: Back view of hand; (b) T710 as syllabogram **ye**: Front view of hand; (c) T710 as logogram ^{SPHERULES}**CHOK**: Back view of hand; (d) T710 as logogram ^{SPHERULES}**CHOK**: Front view of hand; (e) pictorial representation of "throwing" or "scattering" act from Aguateca Stela 1 showing SPHERULES icon. All drawings by the author after unpublished drawings by Ian Graham.

present. Thus, a better way to transliterate the logographic version is ^{SPHERULES}**CHOK**.

An example that is similar to T710 is that of T740 (Figure 7a). This sign has two unrelated orthographic functions and values: logographic **SIJ(YAJ)** for *sihj(-yaj)* 'to be born' and syllabographic **hu**. It is likely that T740 **SIJ(YAJ)** 'be born' actually depicts a frog, while T740 **hu** depicts an iguana. Consequently, their iconic similarity may be due to graphic convergence, a possibility that requires and deserves future diachronic testing. T740 as **SIJ(YAJ)**, the FROG sign, shows a foam-like

Figure 7. T740 in its two functions. (a) ^{FOAM}T740 in spelling of ^{FOAM}**SIJYAJ-ya-ja**; (b) T740 in spelling of **hu-na** 'paper (headband)'. Drawings by Linda Schele. Example of T528 by itself and with semantic determinatives. (c) T128 as logogram **TI'**; (d) T128[501] **'UK'** 'to drink'; (e) T128[506] **WE'** 'to eat'; (f) T128[582] **NUN** (unclear meaning). Drawings by the author after Zender 1999:Figure 20.

substance around the mouth. T740 as **hu**, the IGUANA sign, does not have a foam-like motif. There are exceptions: there are cases of T740 as **SIJ(YAJ)** with no foam-like motif. However, to my knowledge, there are no cases of T740 as **hu** with the foam-like motif. The **hu** value, deciphered by Grube, is widely regarded as derived acrophonically from Proto-Ch'olan **huj* 'iguana'. Thus, the sign most likely depicts an iguana. The foam-like motif, often found in iconographic depictions of frogs, generally distinguishes the two values, and is used on the sign with a logographic value, and thus T740 should be distinguished as follows: ^{FOAM}**SIJ(YAJ)** and **hu**.

Another example is illustrated by the use of T501, T506, and T582, which had logographic (i.e. T501 **HA'**, T506 **WAJ**, T582 **MO'/mo**) and syllabographic (e.g. T501 **b'a**, T582 **mo**) readings of their own. However, these signs could be subfixed to T128, or inserted in the personified form (head-version) of T128, which by itself had the logographic reading **TI'** 'mouth; end' (Figure 7c), as Stuart (1997) and Zender (1999) have shown. In such cases, these signs disambiguated one of at least three possible readings (there were perhaps two other signs that were distinguished by the insertion of one sign in the mouth of a personified T128 sign): T128[501] **'UK'** 'to drink' (Figure 7d), T128[569] **WE'** 'to eat' (Figure 7e), and **NUN** of unclear meaning (Figure 7f). Thus, in these contexts these signs served as semantic determinatives used for disambiguation. At the same time, the personified T128 head with its mouth open, which by itself represents **TI'** 'mouth; end', is clearly also a semantic classifier, since it refers to different activities related in some way or another with the mouth. Neither of the component signs in this graphic compound is read aloud by itself, but instead they determine the reading that the two of them have together.

Zender (1999) has pointed out that these uses correspond closely to the Sumerian composite signs, where, in one instance, a number of different signs (e.g., FOOD, WATER) are placed in the mouth of a head-shaped sign (i.e., HEAD) to produce a number of different logographic readings (e.g., EAT, DRINK). Zender (1999:70) uses the term *relational units* to refer to the Mayan examples, basing it on the common cross-script strategy whereby "organizations of graphic units also commonly represent linguistic units" (Justeson 1978:49). He argues that such relational units are not semantic determinatives. However, his claim is based on an assumption that is unwarranted: he assumes that semantic determinatives serve to semantically disambiguate two or more otherwise homophonous readings of a logogram, and suggests that this is the case in all the scripts where semantic determinatives are used (Zender 1999:42).

Based on this narrow definition of semantic determinatives and their function, Zender (1999) has called into question whether such signs exist in Mayan writing. As discussed above, while some scripts do use semantic determinatives in this way, that is to disambiguate between homophonous readings of a logogram, as in the Egyptian Hieroglyphic case, this is not the only way, in many cases not even the more common way, in which many scripts use semantic signs. Some scripts use semantic signs to classify semantic domains (semantic classifiers); disambiguation (by means of semantic determinatives) is not their primary function. Egyptian Hieroglyphic has semantic classifiers in addition to semantic determinatives. Thus, a broader definition of semantic signs that allows for both determinative (disambiguating) and classifier functions is sufficient to solve the problem. Also, a broader definition of semantic determinatives is required by the cases discussed above; one

where disambiguation is the key, whether it is between a logogram and a syllabogram, or between two different logographic values of the same sign. The crucial point is that such determinatives be used for semantic disambiguation.

Zender (1999:42–43) also suggests that scripts with semantic determinatives require a large number of signs, more than the few hundred that are estimated to have been in use by Mayan scribes at any one time (Grube 1994). Nevertheless, there are several facets of Mayan writing and other scripts that suggest this is not the case; some of these are acknowledged by Zender (1999). First, a single Mayan sign can be polyvalent, a fact that means that there are many more orthographic values in the system than there are signs for: thus T528 could have the logographic values **TUN** 'stone', **CHAHUK/KAWAK** 'lightning', as well as the syllabographic value **ku**. As can be seen with the examples from Figure 5 above, the day sign cartouche and pedestal are diagnostic (i.e., semantic determinatives) of the use of T528 as a day sign. Without them, T528 could have any one of the readings **ku/TUN/HAB'**, but not normally **CHAHUK/KAWAK** 'lightning'. Zender (1999) points out that there are examples of day signs used with their corresponding cartouches (in one example even a day sign pedestal) outside of day sign contexts. He discusses the cases of ^{DAY}T501 used as **b'a**, as in the spelling of **b'a-ka-b'a**, and ^{DAY}T524 used as **HIX** in the spelling of **'IX(IK)-HIX-WITZ-'AJAW**, otherwise spelled also as **HIX-WITZ-'AJAW**.

Second, the argument for the total number of signs in the script as a crucial factor influencing the existence of semantic determinatives is also lessened by cases where signs with values of their own could be used as relational units to combine into composite signs with new values of their own: thus T60 **hi** and T528 **ku/TUN/CHAHUK/KAWAK/HAB'** could be combined graphically as T60:528 and the result was a new composite sign with the syllabographic value **hi**, deciphered by David Stuart. Zender (1999:72) himself notes that these facts (polyvalence, use of signs as relational units to compose new signs) make it very difficult to determine a figure that accurately represents the total number of signs in the script:

> When [composite signs are] considered in tandem with polyphony, one has to wonder whether the *apparent* number of signs in a script are at all related to the number of unique word/concept-signs that a writing system actually has recourse to.

In fact, cross-script comparison suggests that the number of signs in a script has nothing to do with the existence or frequency of use of semantic determinatives. As mentioned, Melchert (personal communication 2004) observes that the total number of Hieroglyphic Luvian signs is about 500, of which only about 200–300 were in use at any given time, yet just about every logogram in the script could be used as a semantic classifier. In the case of Elamite writing, a cuneiform script, "only 100–140 signs are attested" for any period, yet it also made use of semantic determinatives or classifiers (Stolper 2004:67). In both scripts, the classifier signs belonged to the same class of signs used as logograms and, in some cases, to the class of signs used as syllabograms. In such scripts, as in Mayan, a single sign could serve multiple functions.

Zender (1999) uses another piece of evidence to argue against a class of semantic determinatives in Mayan writing. He discusses the uses of the day-sign cartouche (hereafter, DAY), which has been
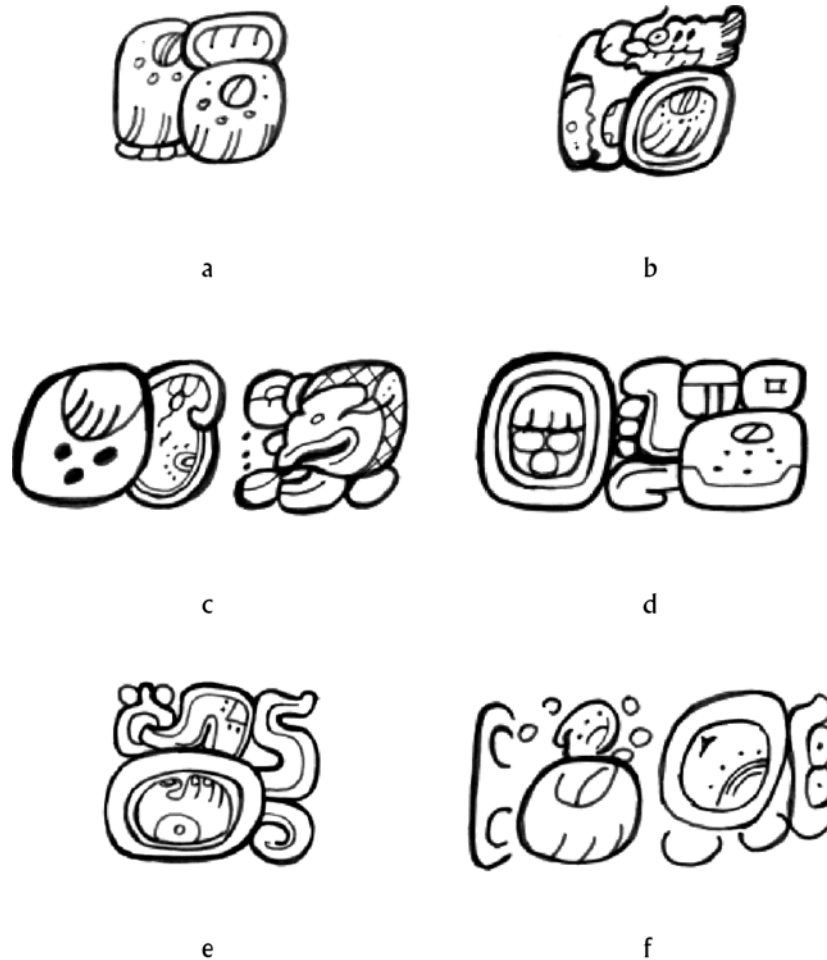

Figure 8. Uses of cartouches outside day0sign context. (a) Typical spelling of title **b'a-ka-b'a**; (b) rare spelling of title **b'a-ka-**^{DAY}**b'a** with cartouched T501 sign; (c) spelling of title **HIX-WITZ 'a-'AJAW-wa**; (d) spelling of same title as ^{DAY}**HIX-wi-tzi 'AJAW**. Drawings by the author after Zender 1999:Figure 8; (e) Glyph D2 on Bonampak Panel. Drawing by the author after Schele 1982:130; (f) Palenque Tablet of the Cross Incensario. Drawing by the author after Schele and Mathews 1979:281.

regarded as the prime example of a semantic determinative in Mayan writing, in contexts where it clearly did not have a calendrical function. The day-sign pedestal is probably a more reliable diagnostic than the day-sign cartouche. To my knowledge there is only one instance of a day sign used with a day-sign pedestal in a non-calendrical context, namely, T524 in a proper name of the same lady whose name is partly illustrated in Figure 8d. Normally, a sign such as T501 could have the values **b'a** or IMIX 'first day of ritual calendar'. However, scribes distinguished the functions of this sign by means of the day-sign cartouche. In a calendrical context, T501 uses the day-sign cartouche (i.e., ^{DAY}T501 for ^{DAY}IMIX, not ^{DAY}**b'a**), while in a non-calendrical context, T501 does not use the day-sign cartouche (i.e., T501 for **b'a**). Zender points out that there are instances in which both T501 **b'a**/^{DAY}IMIX and T524 **HIX**/^{DAY}JAGUAR were used in non-calendrical contexts, with their day-sign cartouches as ^{DAY}**b'a** and ^{DAY}**HIX**, respectively (Figure 8).

In at least one instance, T671 **chi**/^{DAY}MANIK is used with the day-sign cartouche in a non-calendrical context (as ^{DAY}**chi**) (Figure 8e), in the spelling of **'OCH-chi-K'AK'** 's/he fire entered', and in at least one instance, T528 **ku/TUN/**

^{DAY}**CHAHUK**//^{DAY}KAWAK is also used with the day-sign cartouche in a non-calendrical context (as ^{DAY}**TUN**) (Figure 8f). However, such examples are extremely rare. Further, they are unlikely to cause ambiguity due to their contexts. ^{DAY}**b'a** was used in the spelling of **b'a-ka-** ^{DAY}**b'a**, a very frequent title that almost always appears at the end of a nominal phrase containing several titles and epithets. If we compare this example with the dozens of instances in which the distinction was maintained, we must conclude that these rare occurrences were probably of a playful nature rather than a dissolution of the distinction between the calendrical and non-calendrical contexts of the set of signs used as day signs.

DIACHRONIC DEVELOPMENT

The earliest Mayan texts do not show the widespread use of semantic classifiers one sees in later texts. For example, the likely predecessor of T644 **CHUM** attested in the Dumbarton Oaks quartzite pectoral (Figure 9a), which dates to the Late Preclassic period (400 B.C.–A.D. 200) does not bear the semantic classifier for HUMAN that T644 bears in Classic period texts (Figure 9b), as pointed out by Hopkins and Josserand (1999).
Figure 9. (a) Glyph A5 on Dumbarton Oaks quartzite pectoral. Drawing by the author; (b) Classic-period SIT/SEATED glyph. Drawing from Bricker 1986:Figure 187; (c) Glyph A3 on Dumbarton Oaks quartzite pectoral; (d) Glyph 2 on unprovenienced clam-shell jade effigy pectoral (K763); (e) Glyph A1 on the Dumbarton Oaks quartzite pectoral; (f) Glyph B1 on a jade plaque from Costa Rica; (g) Glyph C2 on Pearlman conch shell text; (h) Glyph A5 on diorite axe from Hatzcap Ceel; (i) Glyph B1b on slate mirror-back disk from Jade Museum in Costa Rica; (j) Glyph A3b on tubular jade bead from the Sacred Cenote at Chichen Itza; (k) Glyph A1b on Brooklyn Museum of art pectoral jadeite mask; (l) Glyph D5 on the Dumbarton Oaks quartzite pectoral. All drawings by the author.

In fact, it is not clear that the Dumbarton Oaks quartzite pectoral, undoubtedly one of the earliest Mayan texts, bears any semantic classifiers. One likely candidate is the so-called REFLECTION sign that is used on objects with polished surfaces (Figure 9c–f). It is in fact present on the pectoral, and its evolution can be traced in later texts. The T757 GOPHER sign was discussed earlier in relation to its common infix T281 **K'AN** 'yellow, precious', which Bricker (1986:136) had analyzed as a silent marker used to specify the species of gopher, the yellow pocket gopher, that T757 depicts iconically. The earliest occurrences of this sign do not bear such an infix (Figure 9g–k), also suggesting that it was a later, possibly Early Classic, addition.

As for the distinction between the HUMAN and ANIMAL classifiers, an interesting pattern emerges when it is studied diachronically. As noted earlier, Hopkins and Josserand (1999) propose a circular element to classify a HUMAN category,

while a double-notched element seems to classify an ANIMAL category. This distinction is not present in the earliest texts. For instance, the likely T671 **chi** hand on the Dumbarton Oaks pectoral (Figure 10a) shows a cartouche with no elements inside of it. Nor is there evidence that one once existed but has worn off. There is not a single example on that text of a U- or II-shaped element inside a human or animal sign. Other Late Preclassic texts provide evidence for the U-shaped element on human body parts, particularly hands (Figure 10b–d) or for the II-element on both human and animal body parts (Figure 10e–f). But where do these U- and II-shaped elements come from, and how do they lead to the circular and double-notched elements from the Classic period? Before proceeding along this vein, one more observation is necessary: the HUMAN and ANIMAL classifiers were still not common during the Early Classic period, as can be seen in several cases of the **B'ALAM** 'jaguar' glyph (Figure 10h–i) and cases of signs depicting human hands

Figure 10. (a) Glyph Bla on Dumbarton Oaks quartzite pectoral; (b) glyph on Pomona Flare; (c) glyph on carved stone bowl; (d) glyph on Brooklyn Museum of Art pectoral jadeite mask; (e) glyph on steatite were-jaguar figurine; (f) glyph on steatite were-jaguar figurine; (g) glyph ch'o-ko with Il-shaped element; (h) spelling **CHAK-ka-B'ALAM** on slate mirror-back disk from Jade Museum in Costa Rica; (i) **B'ALAM** 'jaguar' glyph on Early Classic jade pendant from Costa Rica; (j) Glyph A2 on Dumbarton Oaks jade celt fragment; (k) Glyph A2 on Early Classic jade pendant from Costa Rica; (l) Glyph A8 on Early Classic jade pendant from Costa Rica; (m) Glyph A6 on Early Classic jade pendant from Costa Rica. All drawings by the author.

(Figure 10j–l). However, there are interesting cases of other classifiers that are not commonly seen, such as a possible case of the numeral sign FOUR used as a classifier for the Sun God glyph, **K'INICH** (Figure 10m), the same glyph that was used as the head variant of the numeral 'four'.

In Figure 10e–g, a similarity between the ANIMAL, double-notched classifier and the Il-shaped element of the early texts, found with both animal and human body parts, can be

appreciated. Here I argue that animal (Figure 10e) and human (Figure 10f) icons were labeled the same during the Late Preclassic period. The question, then, is: how did they become distinct in later texts?

Part of the answer lies in Lacadena's (1995) seminal study of Mayan paleography, in which he describes an analogical change that spread across all the possible graphic environments, between about A.D. 500 and 600, and that involved all signs that contained
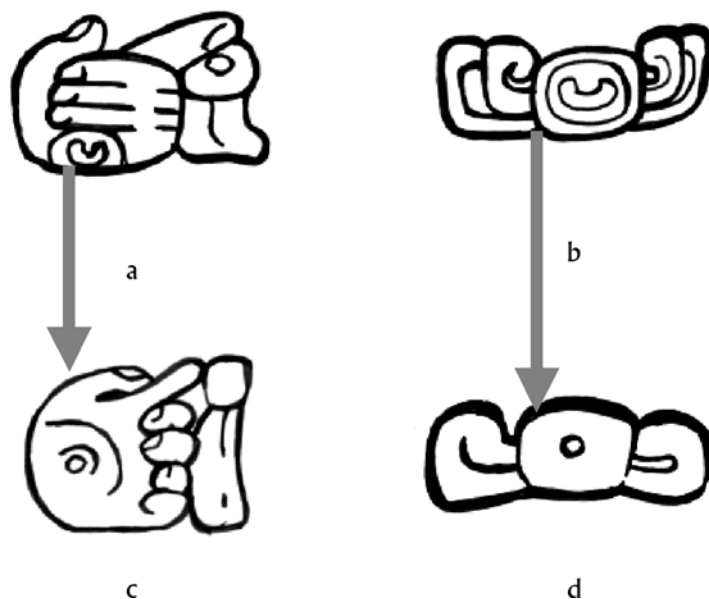

Figure 11. Signs for **TSUTS** 'to finish' and **yu**. (a–b) Early Classic forms with U-shaped elements; (c–d) later forms with O-shaped elements. Drawings from Lacadena 1996:210–211.

a U-shaped iconic element, which changed to an O-shaped iconic element (Figure 11).

As suggested in Mora-Marín (2001), this change apparently took place at different times in the iconographic and glyphic systems. In the iconographic system, the change happened earlier. In fact, a state of variation is observed by A.D. 200 in examples such as the Pomona Flare, as in the iconic elements of the head glyph for **K'INICH** 'Sun God' (Figure 12a–b). This example serves as an iconographic precursor to the later glyphic changes described by Lacadena (Figure 12c–d). Evidence from the Pearlman conch shell, an unprovenienced text that may date to A.D. 400–500 (Schele and Miller 1986), indicates variation in the glyphic system between normal U-shaped elements (Figure 12e) in glyphs and U-shaped elements that show closing into an O-shaped element (Figure 12f).

The second part of the puzzle can be solved by noting that, in the text on the steatite were-jaguar figurine, the U-shaped element clearly visible on one sign (Figure 13a) is very similar to the II-shaped element present on a human hand sign (Figure 13b) and a beheaded jaguar sign (Figure 13c). It is not hard to visualize how the U-shaped element in Figure 13a could easily lead to the II-shaped element if it were placed along the outline of the enclosing cartouche instead of right in its center (Figure 13d–e). Consequently, it is possible that the II-shaped element was simply an artistic variant of the U-shaped element. Significantly, this variation between the II-shaped and U-shaped elements would explain why the Early Classic period human signs use the U-shaped element, when the Late Preclassic period apparently used a II-shaped element. They were both variants of the same, basic sign, but one of the variants was discontinued—for human body parts, at least—while it remained in use for animals. Thus, the double-notched element that classifies animals (Figure 13f) was derived from the II-shaped element that was formerly a variant of the U-shaped element. We are dealing here with a process analogous to a case of phonemic split as defined in historical

linguistics. Supporting evidence for this hypothesis is found in the existing variation in the Pomona Flare, as seen in Figure 13g–h, where the U-shaped element is seen fully contained within a cartouche in one case (Figure 13g), but only partly so in the other case (Figure 13h), in which the U-shaped element was placed long the outline of the cartouche.

What this evidence suggests is that semantic classifiers have developed in tandem with both the iconographic and the glyphic systems. The iconographic variation between U-shaped and O-shaped elements served as the motivation for the eventual change of U-shaped to O-shaped elements in the glyphic system. And this change apparently led to a split of the U- and II-shaped elements, formerly simple variants, to a distinction between O-shaped element for HUMAN and II-shaped elements for ANIMAL.

CONCLUSIONS AND FUTURE RESEARCH

I propose that Mayan scribes distinguished between semantic determinatives (e.g., day-sign cartouche and pedestal; royal headband; T501 vs. T506 when used in combination with T128 **TI'** 'mouth; end') used to distinguish logographic values of signs from other values, on the one hand, and, on the other, semantic classifiers that could be generic (e.g., CIRCLE for 'human', CABAN.CURL for 'earth') or specific (e.g., T251 **K'AN** inside T757 **B'AH**). A plurality of semantic classifiers probably exists, recruited from the ranks of logographic signs in most cases but also, perhaps, from more commonly iconographic signs. Such signs need to be discovered and catalogued not only because epigraphers need to take them into account in the process of decipherment, but also because they can offer a great deal of insight into the historical development of the script.

The data discussed here have a number of implications for the historical development of Mayan writing. One is the possibility that semantic classifiers and determiners could be reinterpreted as logographic signs, which could then be thought of (synchronically and diachronically) in compositional terms—that is, in terms
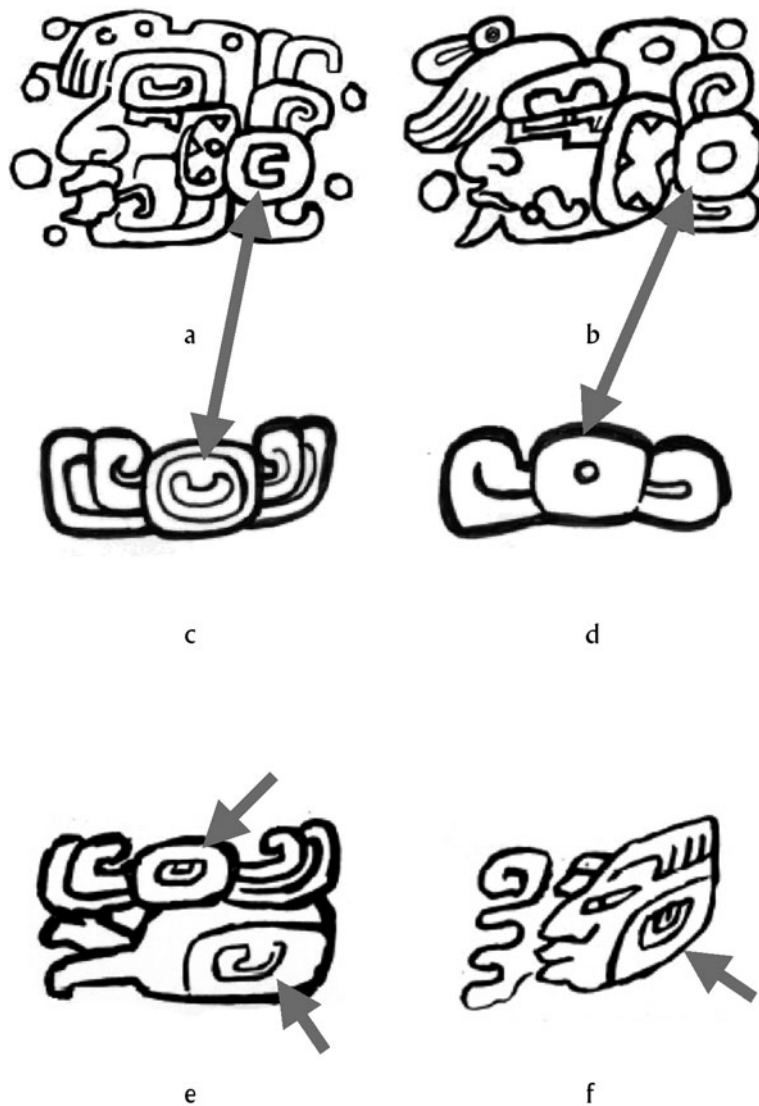

Figure 12. Variation between U- and O-shaped elements in pictorial art (iconography) and the glyphic system. (a—b) Glyph for **K'INICH** 'Sun God' on the Pomona jade earflare. of relational units. This is suggested by the expressions based on T1008, which served as the compositional base for a variety of glyphs such as ^{RH}**'AJAW** and ^{TS}**KELEM**. These apparently were understood as logograms themselves, given the use of phonetic determinatives attached to the *semantic determiner + base* compounded logogram (e.g., ^{RH}**'AJAW-wa**, ^{TS}**KELEM-ma**). And while a graphic composition such as T117.1008 **wi-**PERSON (Figure 10c), involving a logogram preceded by a phonetic determiner, was apparently not made into a compounded logogram itself, there is evidence of "frozen spellings" or "templates" that were based on a sequence of syllabograms which were apparently reinterpreted as a compounded logogram (e.g., **chu[ku]-ka-ja** rather than **chu-ka-ja**, both for *chuk-aj*; **ch'o[ko]-ko** rather than **ch'o-ko**, both for *ch'ok* 'youth, sprout') on which additional syllabograms would be added to spell necessary suffixes, as discussed by Zender (1999) and Tokovinine and Davletshin (2001).

More work is needed to identify spellings of the various types discussed here, especially of cases of full phonetic spellings that precede or follow a logogram. Such spellings are indicative of the use of semantic determinatives and classifiers in other scripts around the world. However, additional contextual analysis in Mayan texts is needed to determine whether they can be described as cases of logograms preceded or followed by full phonetic complements or as cases of semantic signs disambiguating or classifying a phonetically spelled word. What is clear is that statements suggesting that a "pattern of fully syllabic spellings accompanied by logographs is no longer thought to characterize Maya writing" (Houston and Coe 2003:154) are rather premature, and the topic should be problematized and approached systematically, without biases, for not only are such spellings typical of logophonetic scripts, and not exaggerations of scholars, but merely intentional "exaggerations" of the scribes themselves (Kelley 1976:176).

RESUMEN

El presente artículo discute una práctica de deletreo fonético en la escritura jeroglífica maya que no ha recibido suficiente atención: el uso de complementos fonéticos que delimitan en forma completa la lectura de un logograma (por ejemplo, **wa-WAY-ya**, **wa-ya-WAY**, **WAY-wa-ya**, para representar *way*, "nagual, brujo"), en vez de hacerlo en forma parcial (**wa-WAY**, **WAY-ya**), la cual fue la práctica estandarizada. La práctica en cuestión es particularmente inusual cuando los complementos fonéticos se anteponen o posponen por completo al logograma. Tal práctica es común en sistemas de escritura del Viejo Mundo, como en la escritura jeroglífica egipcia, en los cuales se le ha concebido como práctica diagnóstica de la presencia de semantogramas—signos mudos que categorizan los referentes pictóricos, pero no necesariamente lingüísticos—de los logograms con los cuales están asociados en el texto. Además, también se propone una distinción entre dos tipos de semantogramas, o signos de función puramente semántica: determinativos semánticos, los cuales distinguen entre dos valores ortográficos de un mismo signo dado (T710 **ye** vs. [INCIENSO]T710 **CHOK** para representar *chok*, "arrojar (hacia abajo)"), y clasificadores semánticos, los cuales simplemente categorizan a un objeto pictórico (HUMANO en partes del cuerpo humano vs. ANIMAL en partes del cuerpo de un animal). Finalmente se proponen varios ejemplos de cada tipo de signo, e incluso se ofrece un bosquejo de la evolución de varias grafías desde el punto de vista de clasificación de signos propuesto en este artículo.
